(Dated: September 20, 2008)

It is shown that the before-before (or Suarez-Scarani) experiment refutes hidden variable models with a deterministic (“realistic”) nonlocal part, and the experimental violation of Leggett-type inequalities models with a random nonlocal part and a biased random local one. Therefore the claim that Gröblacher et al. present “an experimental test of nonlocal realism” [1] is misleading, and Marek Żukowski’s comment [2] misses the point. A new experiment is proposed.

In a recent comment [2] Marek Żukowski, co-author of Reference [1], claims that I wrongly present in Reference [3] the assumptions behind the Leggett’s inequalities, and their modified form used by Gröblacher et al. [1] for an experimental falsification of a certain class of non-local hidden variable models. Nevertheless, Żukowski’s writes that his comment “is not aimed at a detailed discussion of the arguments given by Suarez” [2].

By omitting details Żukowski’s comment misses the point. What I state is this:

The authors of [1] do not only say that their experiment violates the Leggett’s inequalities, but also claim that it is “an experimental test of nonlocal realism”. More specifically, they claim that their result “excludes for the first time a broad class of non-local hidden-variable theories” [1].

Against this claim I argue:

1) The before-before experiment [4, 5, 6] was first in excluding a class of nonlocal hidden variable theories, and thus “nonlocal realism”.

2) Gröblacher et al. did not test “nonlocal realism”.

Regarding 1)

Bell type experiments refuted local hidden variable models. However, by adding nonlocal hidden variables it is still possible to save determinism (see, e.g., [7]). This is the case in the Suarez-Scarani model [4, 5, 8]. This model uses moving measuring devices, and thereby different relativistic timings. It assumes time-ordered nonlocal dependencies (nonlocal determinism) for certain timings, and only local hidden variables (local determinism) for the before-before timing. This leads to conflict with the timing independence of quantum mechanics. The before-before experiment falsified the nonlocal deterministic model of Suarez-Scarani, and confirmed the quantum prediction [5, 6].

Thus, the Suarez-Scarani experiment was first in excluding nonlocal hidden variable models. It showed that, to borrow a phrase from [1], “giving up the concept of

locality is not sufficient to be consistent with quantum experiments”.

“Realism” as defined in Reference [1] has the meaning of determinism. I do not say that Gröblacher et al. support “gender asymmetry” [2], but nonlocal determinism [9]. They assume that Alice’s outcome is nonlocally *predetermined* by Bob’s one, or Bob’s outcome by Alice’s one. The “explicit toy non-local model” [2] Gröblacher et al. propose clearly shows that they have nonlocal deterministic models in mind (toys are usually good indicators of cognitive structures).

Thus, the model described in Reference [1] can be considered refuted by the before-before experiment (unless one postulates a single preferred frame what, on the one hand, is not the case in [1], and on the other hand, bears severe oddities [3]).

Regarding 2)

In Leggett models the hidden variables have always a local and a nonlocal part [10, 11], independently of any timing.

As soon as one assumes a *deterministic nonlocal* part, the Suarez-Scarani experiment becomes obviously relevant for Leggett’s models and refutes them.

Thus, the specific aim of experiments testing Leggett-type inequalities is to test models exhibiting *nonlocal randomness*, and non-trivial local parts, i.e., outcomes that depend on biased random local variables [10, 11].

This means that Gröblacher et al., in spite of assuming “nonlocal realism”, in fact did not test this assumption.

Certainly, their experiment [1] (as far as its implementation is correct) would also rule out a model without determinism in the nonlocal part, and so is useful in addition to the before-before experiment when interpreted correctly [13]. And in any case, has the merit of priority as a proposal to test Leggett inequalities.

Conclusion and proposal for a new experiment

The Suarez-Scarani (before-before) experiment excludes *time-order* or determinism in the nonlocal part. That is, the quantum correlations come from outside

spacetime through free choices in Nature (God plays dice) [12].

Leggett experiments demonstrate that Nature refuses even to *mimic* certain deterministic (“realistic”) features by means of biased random local variables (God plays *fair* dice).

Putting together the results of both types of experiments one can conclude that Nature is not less random than predicted by quantum mechanics. [14]

Nevertheless, to date the results supporting this conclusion have been gathered in separated experiments. It would be suitable to refute both determinism and biased randomness by one and the same experiment. I think this may be nicely done by a before-before version of the experiment described by Colbeck and Renner [11]. The new experiment would basically consist in demonstrating *firstly*, that Nature exhibits correlations originating from pure nonlocal links and *secondly*, these links are not time-ordered. Work exploring this

possibility is in progress. Such an experiment would definitely contribute to a better understanding of the quantum.

Request: Though the Suarez-Scarani experiment was first in testing nonlocal determinism and excluding nonlocal hidden variable models, the experiment was not quoted in Reference [1]. Thereby Gröblacher et al. overlooked relevant work and advanced a misleading interpretation of their own results. I think *Nature’s* general audience deserves to be informed about this state of affairs, and kindly request Anton Zeilinger and the Editor to agree in publishing a clarifying comment.

Acknowledgments: I am grateful to Marek Żukowski for his stimulating comment, and Cyril Branciard, Časlav Brukner, Roger Colbeck, Bernard d’Espagnat, Nicolas Gisin, Valerio Scarani, Hugo Zbinden for discussions on the subject.
